Introduction

The Metropolitan Area Planning Agency (MAPA) produces a biennial *Regional Traffic Patterns Report,* an analysis of regional and sub-regional traffic patterns, in conjunction with the *Traffic Flow Map*, the *Top Traffic Intersections Report*, and the *Top Interchange Report*. This report compares the regional traffic patterns for vehicular, freight, and multi-modal transportation.

Traffic Analysis Districts

This report measures the changes in traffic patterns at regional and sub-regional levels. Traffic count data is aggregated to the Traffic Analysis Districts (TAD); small areas in each county that are bounded by major roadways as shown in Figure 1.

Figure 1: *Traffic Analysis District Map*

Observations 2022-2025

Traffic observations are shown as vehicle miles traveled (VMT), calculated by multiplying a road segment's length (miles) by average annual daily traffic (AADT). Statistics in the *Regional Traffic Patterns Report* are primarily derived from volumes shown on the *Traffic Flow Map*. For more specific information regarding traffic along or through particular streets or intersections, please consult the *Traffic Data Portal*.

Average Daily Vehicle Miles Traveled

Total VMT is calculated from traffic count estimates, which include new counts as well as older data that has been factored and interpolated. For the first time, this report includes estimates on all roads, utilizing traffic volume data from the Streetlight Insight planning tools.

Figure 2: *2025 Average Daily Vehicle Miles Traveled (in thousands)*

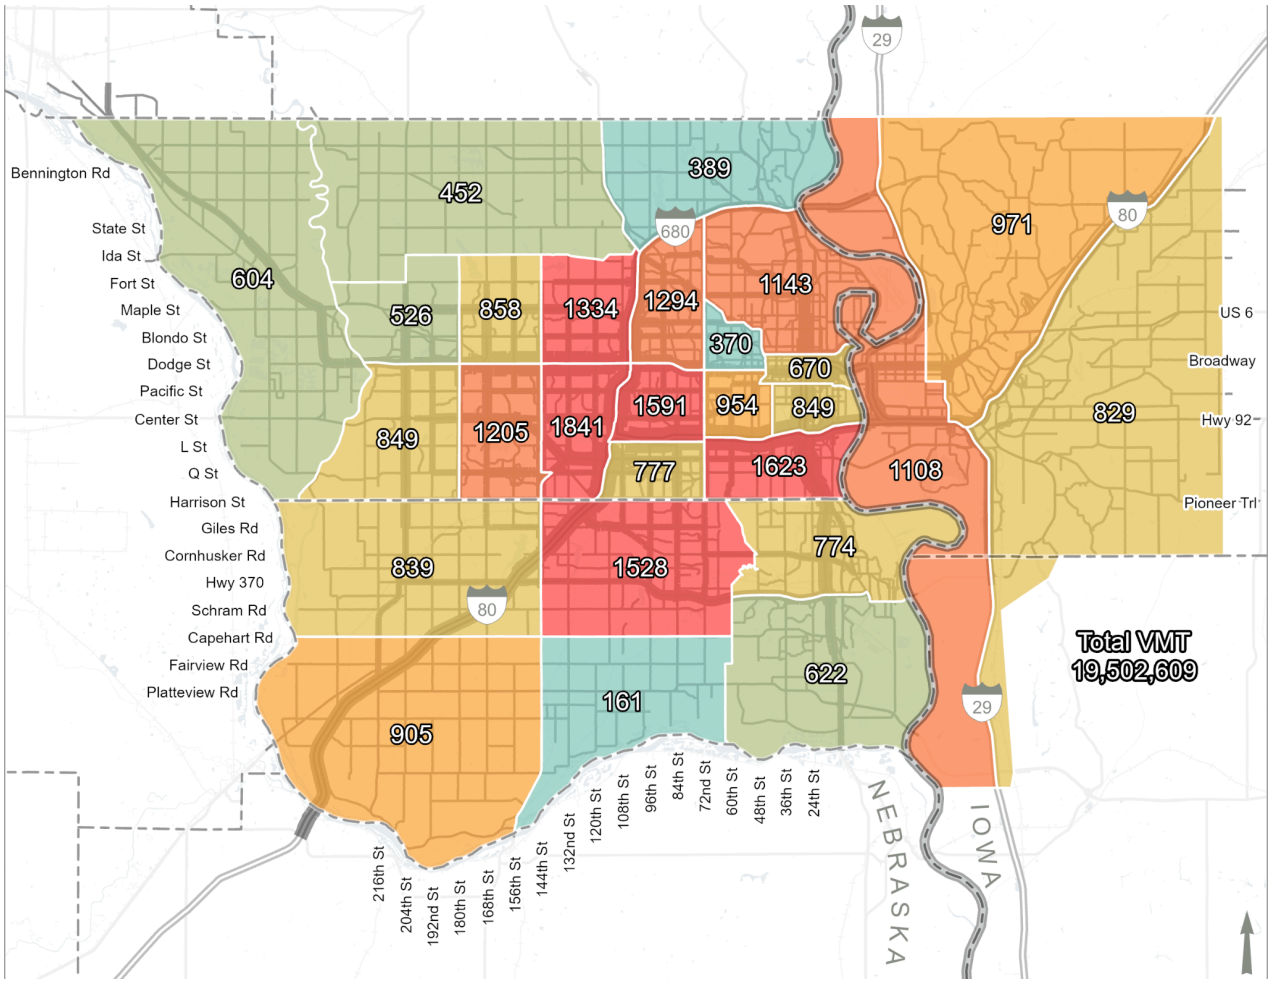

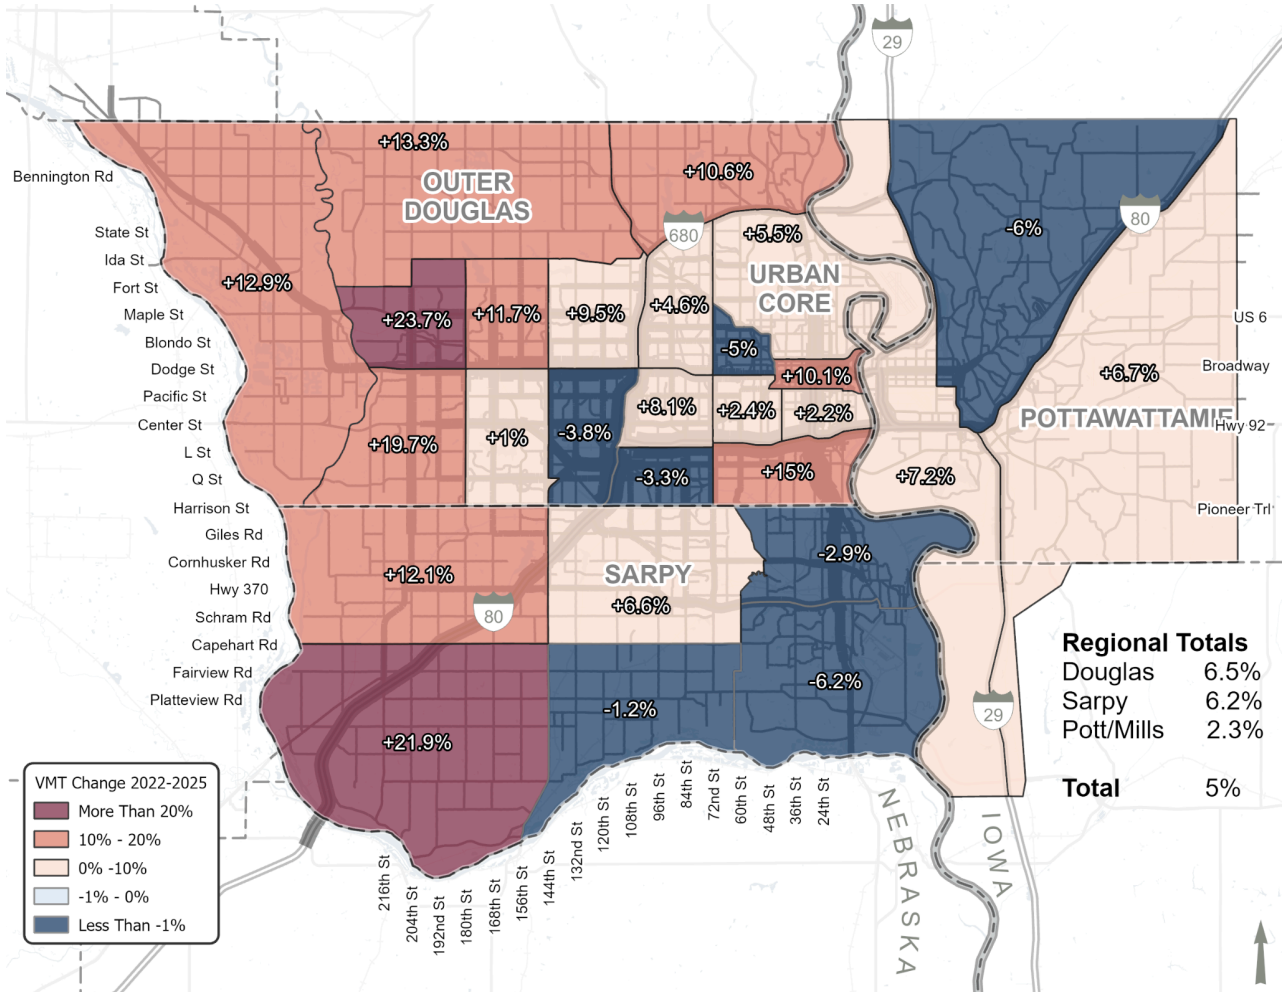

Figure 2 shows average daily vehicle miles traveled, expressed in thousands. StreetLight traffic estimates were adjusted using available short duration and continuous traffic counts. Where enough counts were available, adjustment factors were calculated for each Federal Functional Classification (FFC) within a TAD. Regional factors were used where local counts were limited. The adjusted volumes were checked for consistency along each corridor and across years. This review considered travel direction, divided roadways, and traffic entering or leaving at intersections. Observed counts were given priority when resolving differences.

Change in Vehicle Miles Traveled

VMT is compared between reporting years for each TAD to calculate the rate of change. Figure 3 depicts these district-level rates of change for 2022-2025.

Figure 3: *Estimated Percent Change in VMT 2022-2025*

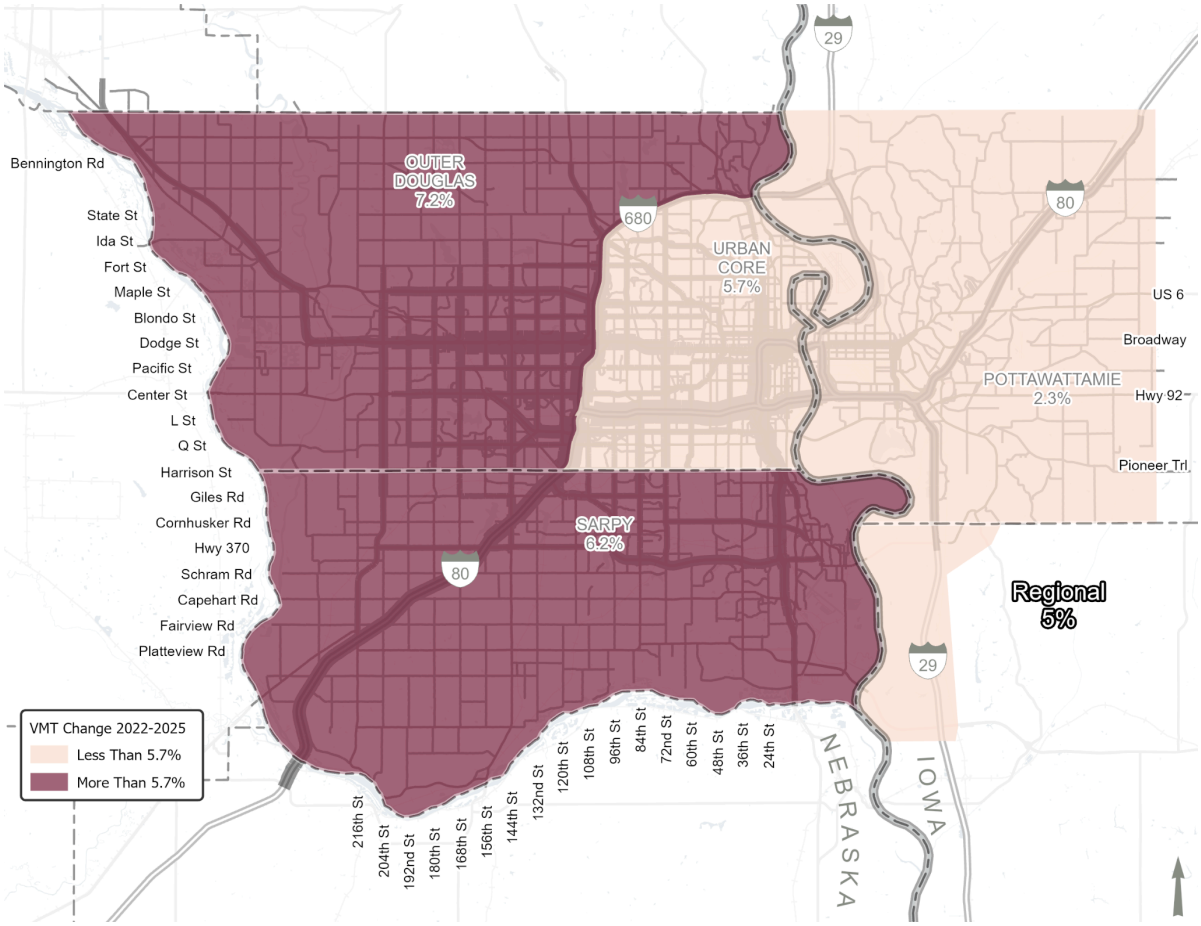

As shown in Figure 4, estimated VMT in Douglas County rose by 6.5% between 2022 and 2025. Outer Douglas County grew by 7.2%, compared with 5.7% in the urban core. VMT increased by

6.2% in Sarpy County and 2.3% in Pottawattamie and Mills Counties. Across the region, the increase was approximately 5%, compared with roughly 13% between 2020 and 2022. Western Douglas and southwestern Sarpy Counties had the largest increases, with several districts exceeding 10%. Continued development in these areas may help explain the additional travel.

Some central Omaha districts recorded decreases despite the overall increase in the urban core. Utility work for the streetcar project and restrictions along Farnam and Harney Streets may have shifted traffic to nearby routes. Lower VMT in these districts could therefore reflect temporary changes in where people drove, rather than a lasting reduction in travel. This report did not measure the effect of construction on those changes.

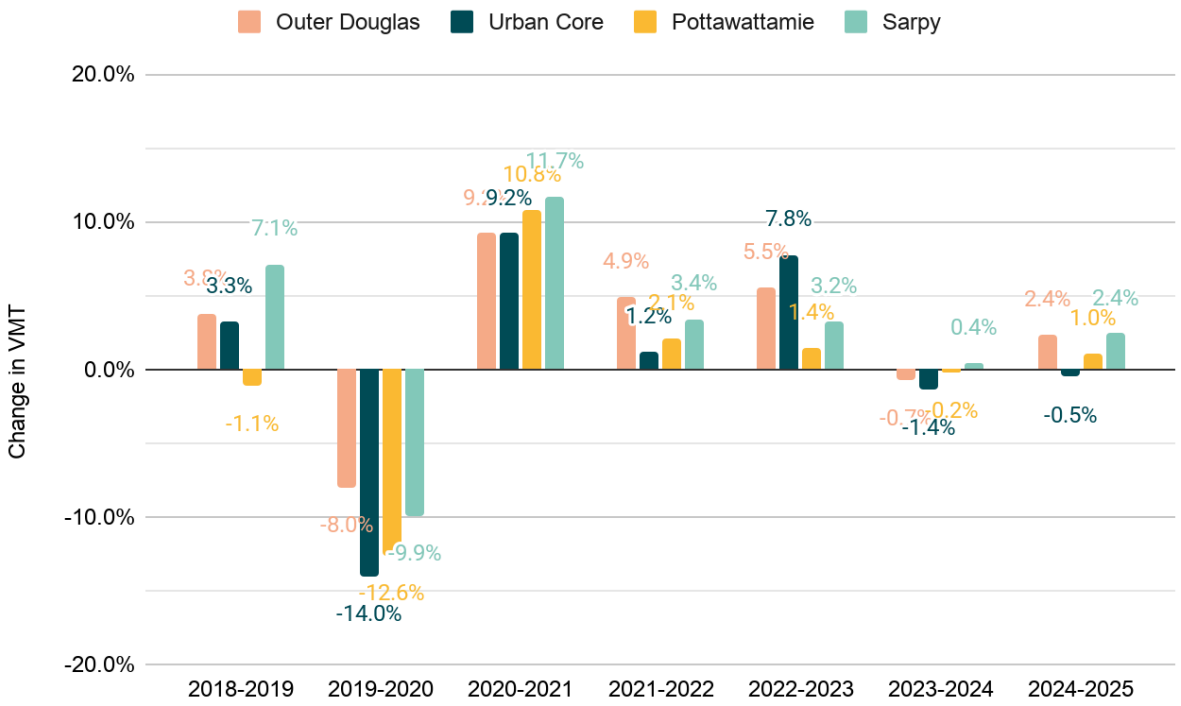

Figure 4: *Regional Percent Change in VMT 2022 - 2025*

Traffic in the MAPA region rebounded in 2021 as travel resumed following COVID-19 restrictions. Figure 5 shows another strong increase in 2023, when VMT in the urban core rose by 7.8%. That increase was followed by declines of 1.4% in 2024 and 0.5% in 2025. Construction discussed earlier may explain part of the decrease. Changes in commuting, including hybrid work and office occupancy, may also have played a role.

Outer Douglas and Pottawattamie Counties recorded small declines in 2024, then grew again in 2025. Sarpy County was the only subregion where VMT increased each year from 2022 through 2025. Growth there slowed to 0.4% in 2024 before reaching 2.4% in 2025. By the end of the reporting period, traffic was increasing outside the urban core, while VMT within the core remained slightly below its 2023 level.

Figure 5: *Annual Percent Change in VMT 2020 - 2025*

As discussed earlier, estimated traffic volumes were calibrated using observed counts, with adjustment factors applied by FFC and TAD, supplemented by regional factors. The following table presents annual changes in VMT by functional classification and identifies the transition from the legacy centerline network to the OSM network.

Table 1: Change in VMT by Federal Functional Classification, 2018-2025

Federal Functional Classification	Legacy methodology - centerline network					2022-2023 Methodology break	New methodology - OSM network		
	Centerline Miles	2018-2019	2019-2020	2020-2021	2021-2022		OSM Network Miles	2023-2024	2024-2025
Interstate	189	2.0%	-16.3%	14.9%	2.8%	N/A	265	-0.4%	0.1%
Freeway	133	2.4%	-7.3%	11.4%	6.5%	N/A	196	1.6%	3.5%
Major Arterial	182	3.1%	-11.7%	7.3%	2.3%	N/A	342	-0.9%	1.9%
Minor Arterial	391	4.9%	-9.0%	6.8%	0.5%	N/A	489	-1.5%	-1.5%
Major Collector	375	14.8%	-10.8%	8.3%	-2.2%	N/A	474	1.5%	3.5%
Minor Collector	151	27.2%	-14.1%	8.4%	1.7%	N/A	197	1.7%	4.1%
Local	554	-3.0%	-3.3%	3.1%	1.8%	N/A	3,908	-5.1%	8.3%

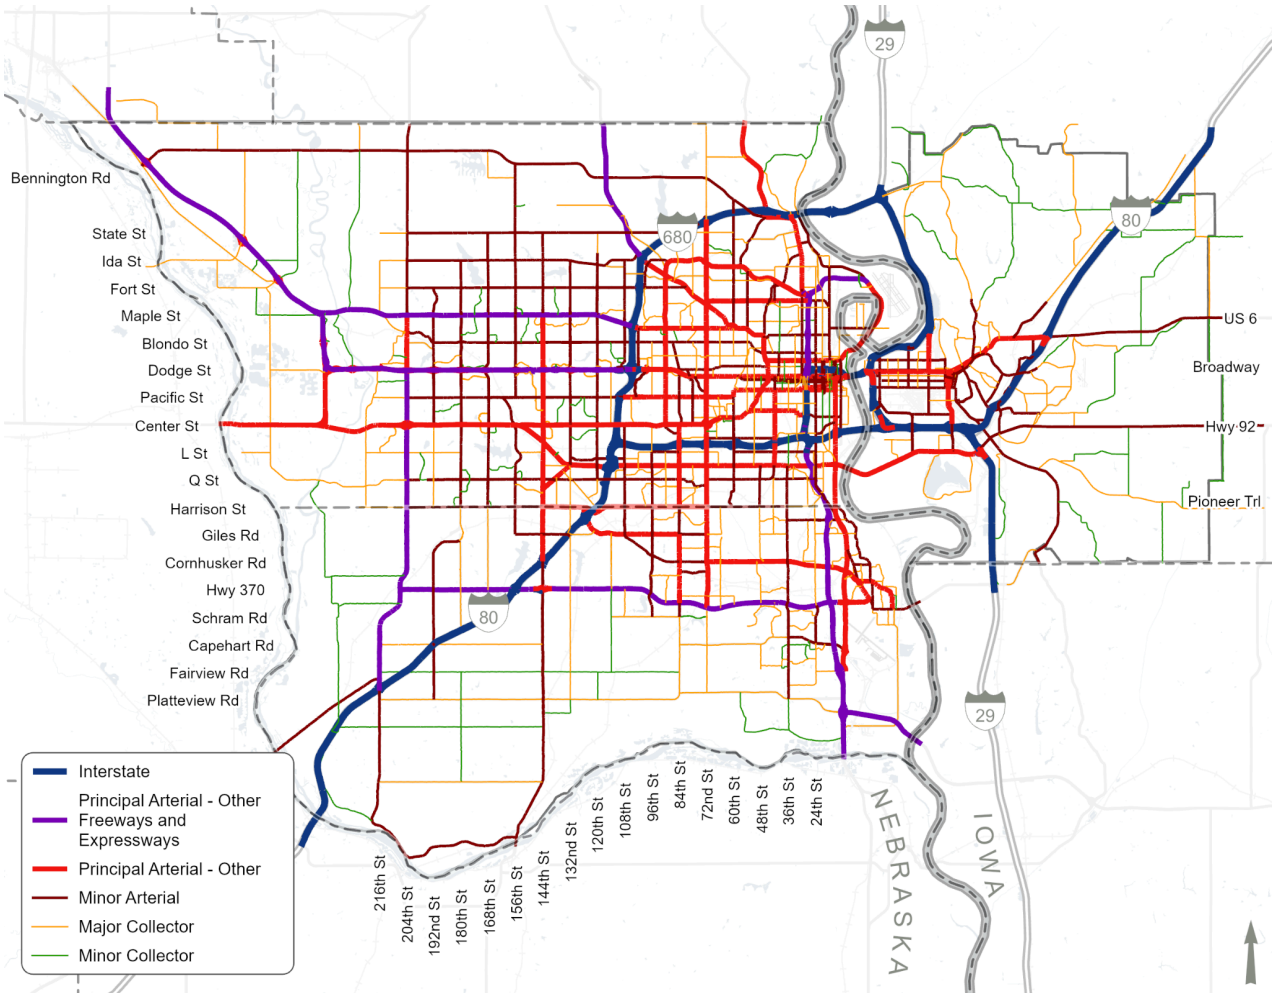

Table 1 illustrates how VMT changed over time by FFC. A street's functional classification reflects its role in moving traffic and providing access to adjacent land uses.
Higher level facilities such as freeways and expressways have lower access, which allows higher speeds and capacities. Conversely, lower level facilities such as local streets and minor collectors allow for greater access, but have reduced mobility due to lower speeds and capacities. This analysis includes every classified road; however, for 2018-2022, only a selection of Local roadways was included because traffic data collection is limited on Local roadways.

From 2023-2025, local roadway information became available, so we implemented a new methodology. In addition, the Open Street Map architecture provides directional information for each road segment, allowing the roadway mileage evaluation to be measured in network, instead of centerline, miles.

The Federal Highway Administration (FHWA) defines these classifications. Regional classifications are illustrated in Figure 6 below.

Figure 6: *Federal Functional Classification*

MAPA Area Continuous Traffic Counts

Nebraska and Iowa both have traffic counting sites that count vehicles on a continuous basis, 365 days a year, in the Omaha-Council Bluffs metro area. These counters, called Automatic Traffic Recorders (ATRs) or Continuous Count Sites (CCS), provide an excellent source of traffic data for analysis. There are currently 15 active ATRs in the region, with 10 located in Nebraska and 5 located in Iowa. A summary of the counter locations is shown in Table 2. Since the last report, ATR 110 in Iowa is no longer counting, and Nebraska added a new counter (A-78) on West Dodge Rd (US-6) between 180th and 192nd Streets.

Table 2: MAPA Regional ATR Summary

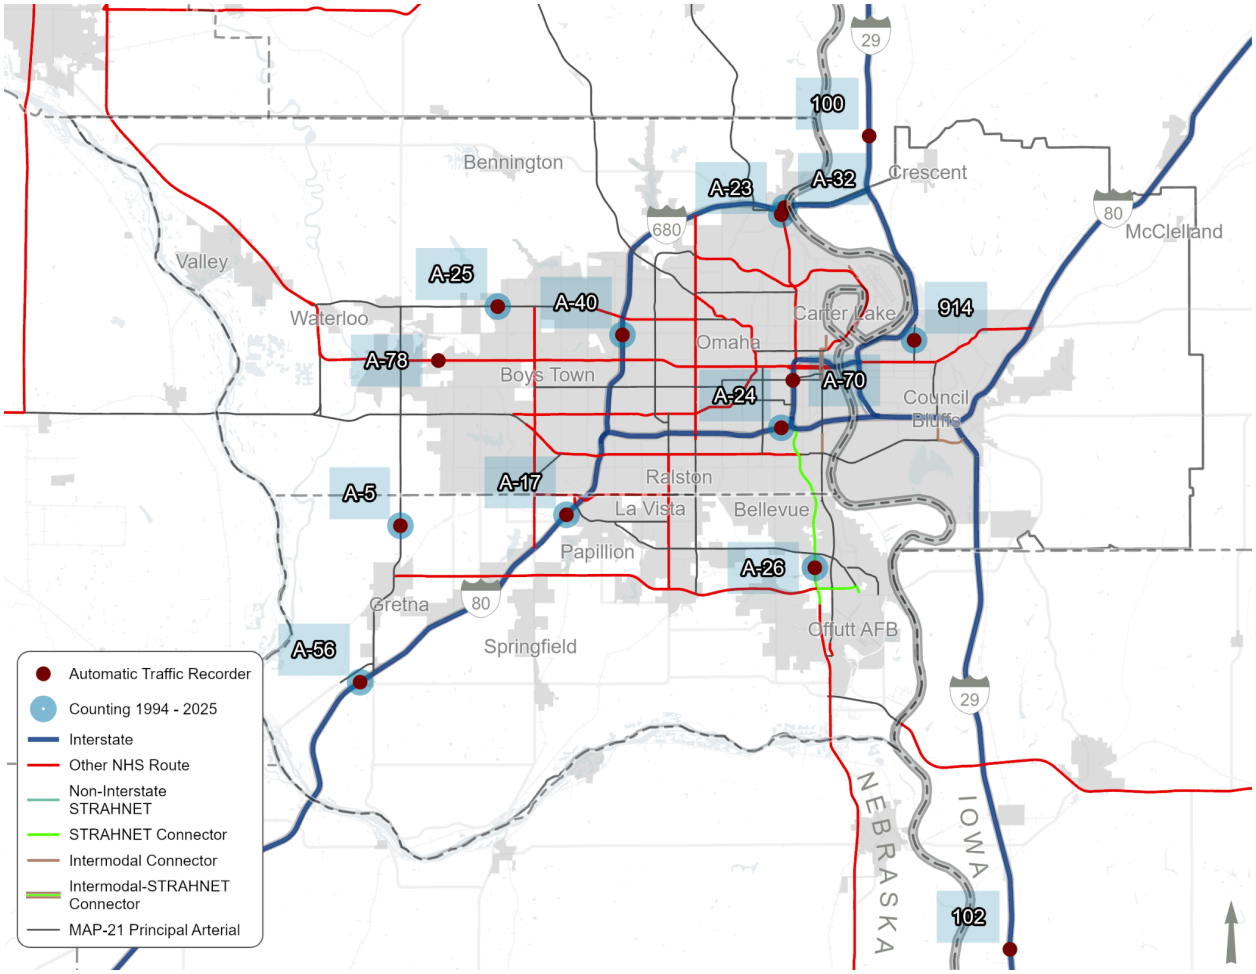

State	ID	Route	Federal Functional Classification	Location
Iowa	100	I-29	Rural Interstate	2 Mi North of South I-680 Jct
	102	I-29	Rural Interstate	7 Mi South of US-34 Jct (Pacific)
	124	I-880	Rural Interstate	6.4 Mi West of I-80 (Beebeetown)
	914	16th St	Municipal Streets	0.6 Mi West of IA-192
Nebraska	A-5	US 6	Principal Arterial	North of Gretna
	A-17	I-80	Urban Interstate	Just South of Douglas-Sarpy Line
	A-23	US 75	Principal Arterial	30th Street South of I-680 in Omaha
	A-24	I-80	Urban Interstate	I-80 at 36th Street in Omaha
	A-25	N-64	Principal Arterial	At 160th Street
	A-26	US 75	Principal Arterial	Just North of Jct. N-370 in Bellevue
	A-32	I-680	Urban Interstate	Mormon Bridge in Omaha
	A-40	I-680	Urban Interstate	I-680 North of Dodge Street
	A-56	I-80	Rural Interstate	West of Gretna Interchange
	A-70	I-480	Urban Interstate	At Leavenworth St in Omaha
	A-78	US-6	Urban Freeway	Between 180th and 192nd St
Locations which have been counted continuously since 1994				

Statewide, ATRs are located on all classes of roadways, from interstate and state highways to local primary and secondary roads. Located in both urban and rural areas, these counters help identify trends in traffic volume growth or decline.

The map below shows the location of ATRs that are either within the MAPA Metropolitan Planning Organization (MPO) Transportation Management Area (TMA), or are in close enough proximity to add value in assessing traffic growth.

Figure 7: *Automatic Traffic Recorder (ATR) Location Map*

Seasonal Variation

Traffic volumes vary significantly throughout the year and are impacted by weather conditions, school sessions, road construction or detours, and holiday travel. This variation is measured both at the monthly and daily periods, and is used to seasonally adjust short-duration traffic counts to be expressed in terms of AADT. Traffic patterns are analyzed across road types and, for our region, binned within the four classifications shown below.

Figure 8: *Monthly Average Daily Traffic (MADT) on Principal Arterials*

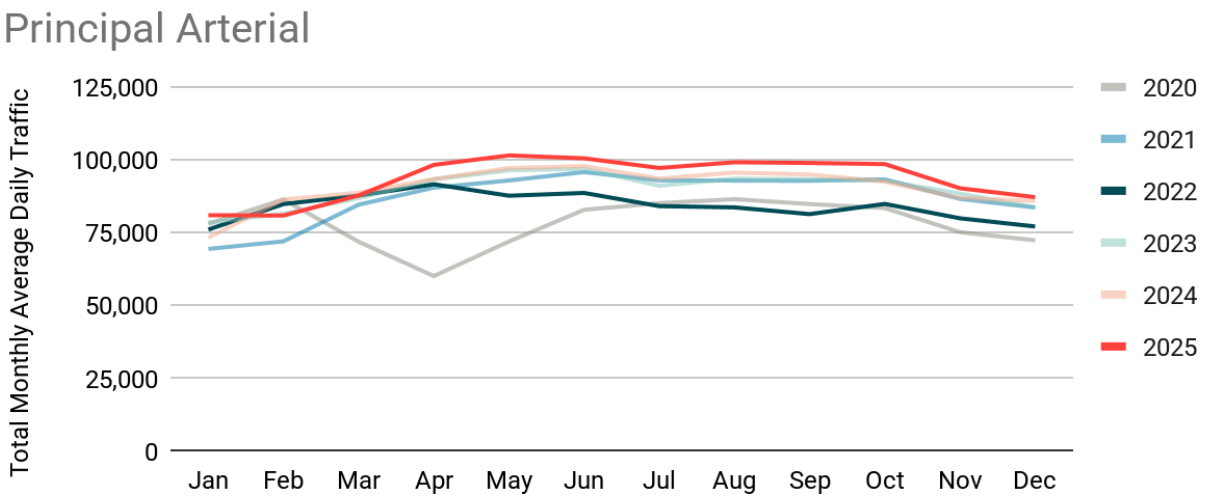

Figure 8 shows monthly traffic at the principal arterial count locations from 2020 through 2025. Traffic recovered after the drop in spring 2020 and has generally risen since 2022. In 2025, monthly average daily traffic was higher than in earlier years except in February and March. The busiest months were typically from late spring through early fall, with lower volumes toward the end of the year.

Growth around Gretna may account for some of the increase on US 6, a connection between western Omaha and I-80. The Sarpy I-80 PEL study also notes increasing traffic demand along this route. Elsewhere, roadwork may have affected the counts. Pavement and bridge repairs on US 75 through Bellevue began in August 2024, bringing overnight lane and ramp closures that may have shifted some traffic to other roads. These are possible influences, but the combined totals do not show whether traffic increased at every location.

Figure 9: *Monthly Average Daily Traffic (MADT) on Municipal Streets*

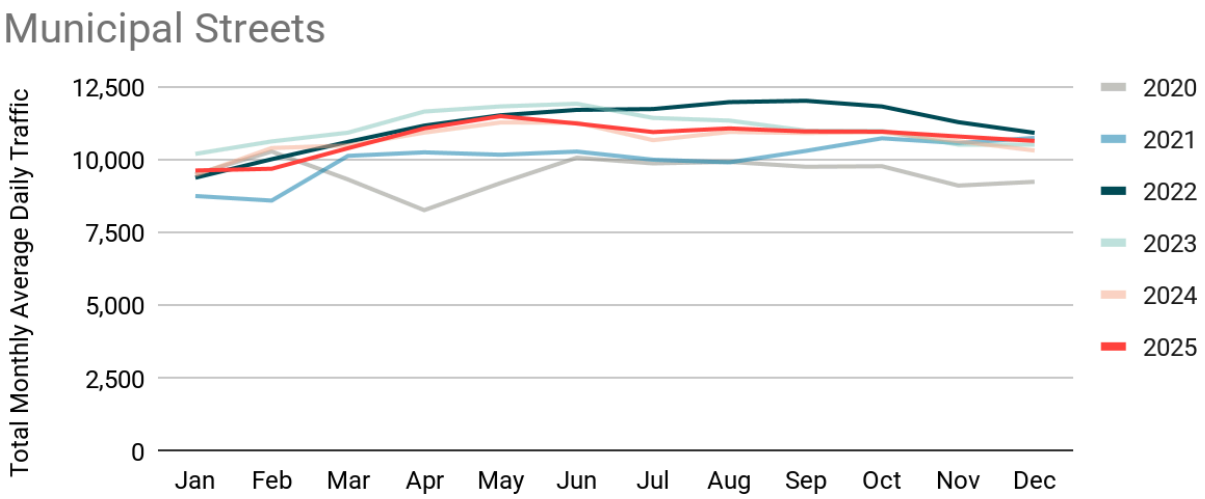

Figure 9 shows monthly traffic volumes on 16th Street in Council Bluffs from 2020 through 2025. Following the decline in spring 2020, traffic recovered in 2021 and remained generally higher in 2022 and 2023. These volumes may have been influenced by the nearby I-29 reconstruction, with phased closures beginning in late 2021 and both directions reopening in August 2023. The lower volumes in 2024 and 2025 may partly reflect traffic returning to I-29 after construction, rather than a sustained decrease in travel.

Figure 10: *Monthly Average Daily Traffic (MADT) on Rural Interstate*

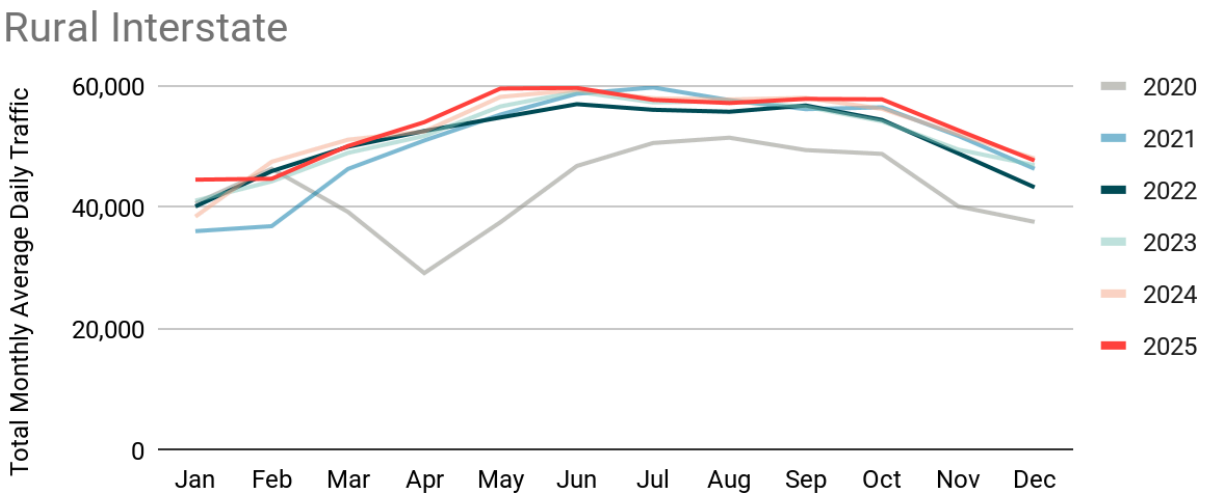

Figure 10 shows that traffic on I-80 west of the Gretna interchange is busiest from May through October and lighter during winter. Vacation and recreational trips may account for part of this difference. National data show a similar pattern, with rural interstates carrying a larger share of

their annual traffic during summer than urban interstates (Federal Highway Administration, 2026).

The monthly counts have changed little since 2022. Although 2025 volumes were among the highest shown, particularly in January and late spring, the differences between recent years were generally small. At this location, the change from winter to summer is more noticeable than the growth from one year to the next.

Figure 11. *Monthly Average Daily Traffic (MADT) on Urban Interstate*

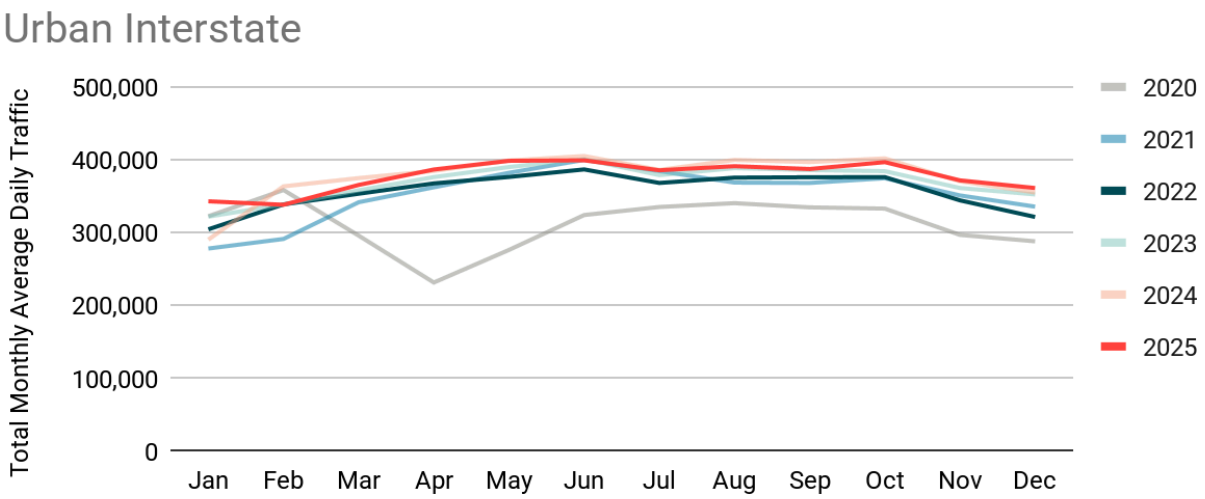

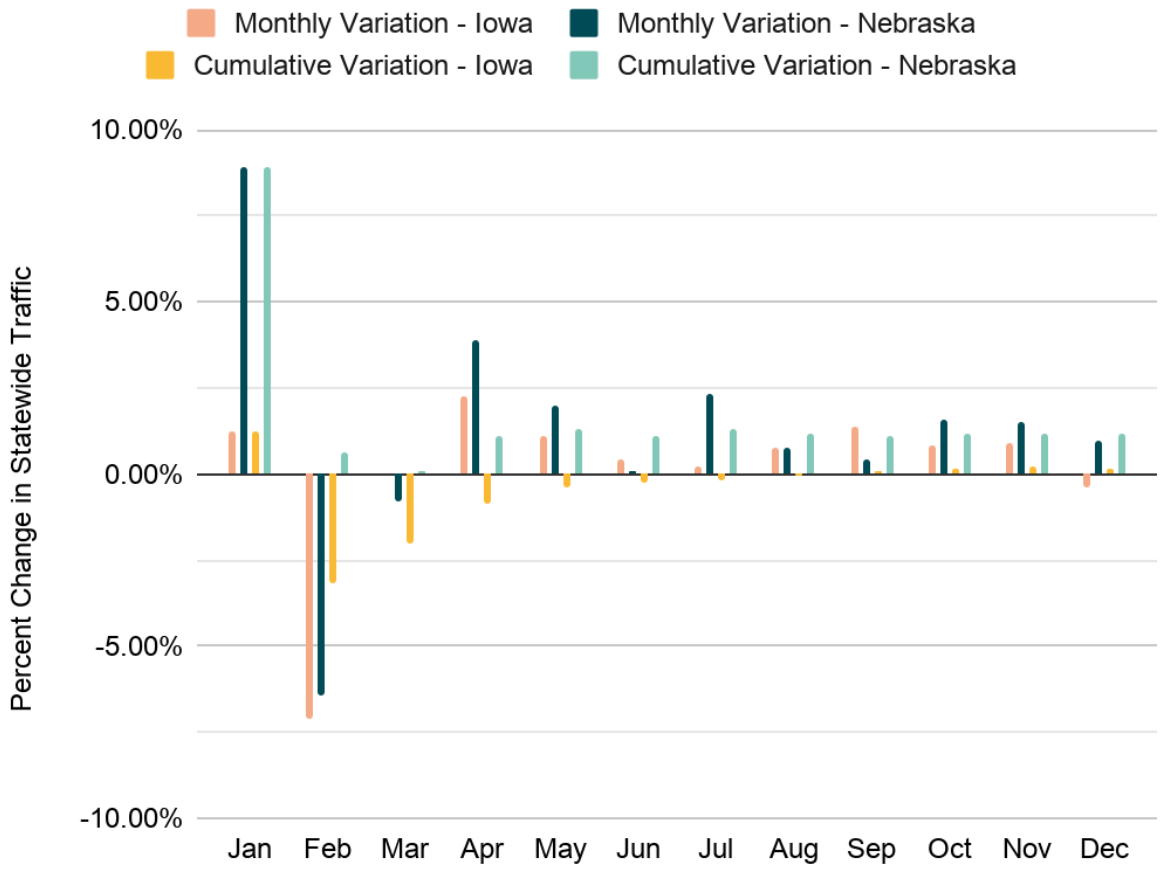

Figure 11 combines monthly average daily traffic from the count locations on I-80, I-680, and I-480. Traffic in 2024 and 2025 was generally higher than in 2022 and 2023, though the increases were small. The highest combined volumes in 2025 occurred in June and October, with little change during the intervening months.

These routes carry daily trips within Omaha as well as traffic passing through the region. Regular commuting may help explain why volumes vary less by season than at the rural interstate location. National data show that urban interstate traffic is more concentrated on weekdays, with morning and afternoon commuting peaks (Federal Highway Administration, 2026). Individual locations may have different trends that are not apparent in the combined totals.

Figure 12: *Monthly and Cumulative Percent Change in Statewide Traffic 2025-2024*

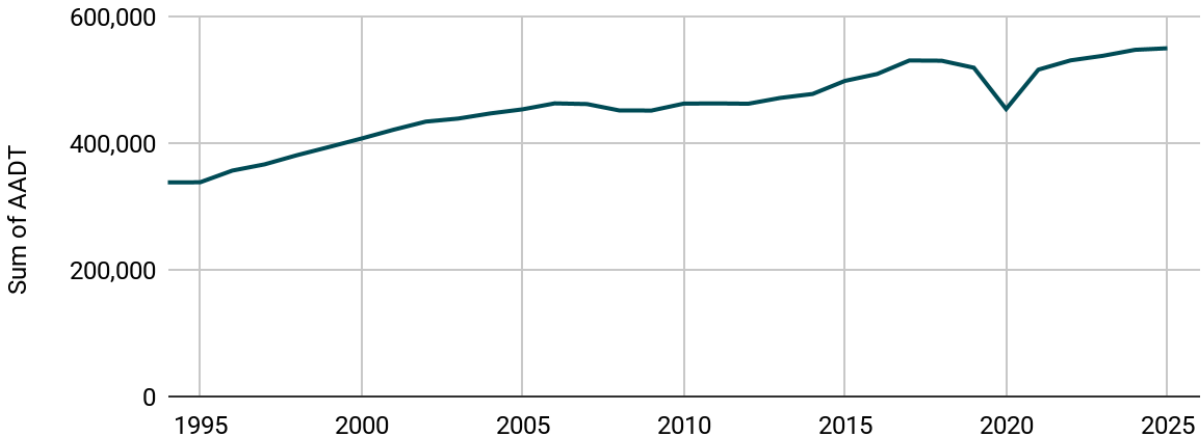

The data presented in Figure 12 above were taken from the monthly Automatic Traffic Recorder reports through December 2025 on the NDOT and IowaDOT websites. This is preliminary data that is finalized at the end of the year in each state's annual report. Nebraska appears to have had a much milder January 2025 and saw significantly higher volumes. Both Iowa and Nebraska saw fairly significant monthly drops in February. Overall, Nebraska ended up with 1.2% cumulative variation in 2025 (fairly consistent with MAPA regional trends), with Iowa seeing a smaller increase of 0.19%.

Long Term Trends

Ten of the fifteen active regional ATRs have been in service and counting since 1994. Figure 13 shows the sum of AADT values for these counters annually. These counters provide historical data within Iowa and Nebraska, and provide coverage of urban and rural interstate, highway, and a municipal street.

Figure 13: *Total Historical ATR Annual Average Daily Traffic by Year*

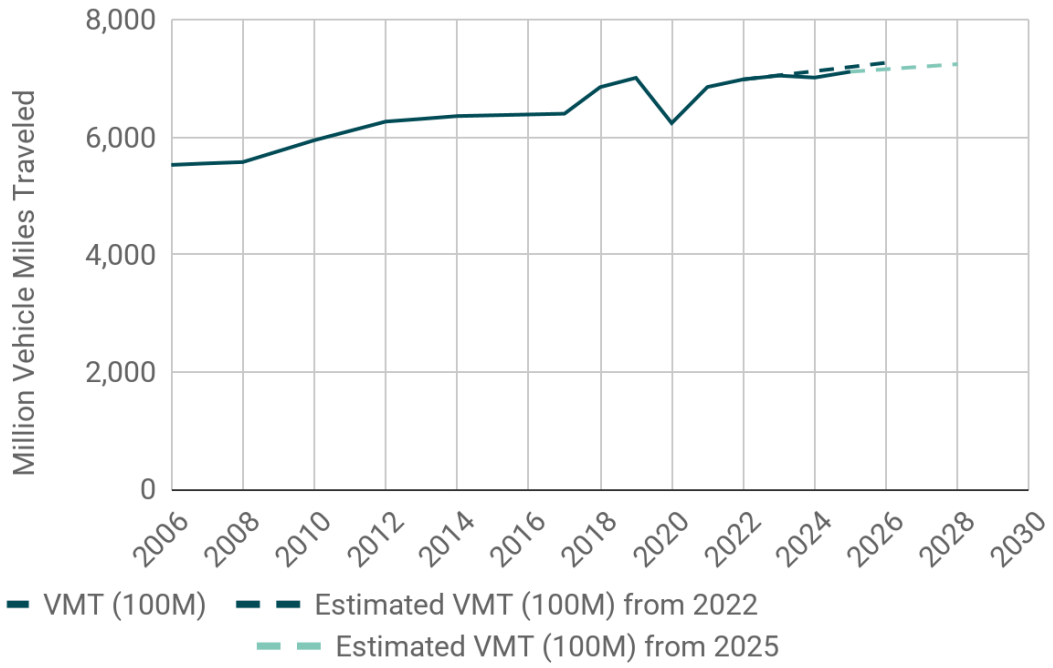

MAPA Regional VMT

Regional VMT is an important metric that helps MAPA support member jurisdictions with transportation planning. The annual VMT is used to calculate the rate of fatalities and serious injuries per 100 million vehicle miles traveled (100M VMT). For more specific information, please consult the *MAPA Performance Dashboard*.

Figure 14 below presents historic VMT through 2025, with an estimated future VMT based on projected traffic increases in the region. After assessing trends in the 2022 Regional Traffic Patterns report, we set a 1% annual VMT growth rate to support safety performance metric target setting.

Figure 14: *MAPA Regional VMT by Year (Measured and Estimated)*

The region did not experience this growth rate; instead, it averaged 0.6% annual growth from 2022 to 2025. This 0.6% growth rate is applied to illustrate possible increases from 2025-2028 as shown in Table 3.

Table 3: MAPA Regional VMT by Year (Measured and Estimated)

Year	100M VMT	Year	100M VMT	Year	100M VMT
2006	5,531	2015	6,376	2024	7,018
2007	5,557	2016	6,389	2025	7,118
2008	5,579	2017	6,403	2026	7,161
2009	5,765	2018	6,856	2027	7,204
2010	5,951	2019	7,014	2028	7,247
2011	6,110	2020	6,242		
2012	6,269	2021	6,858		
2013	6,314	2022	6,987		
2014	6,363	2023	7,052		

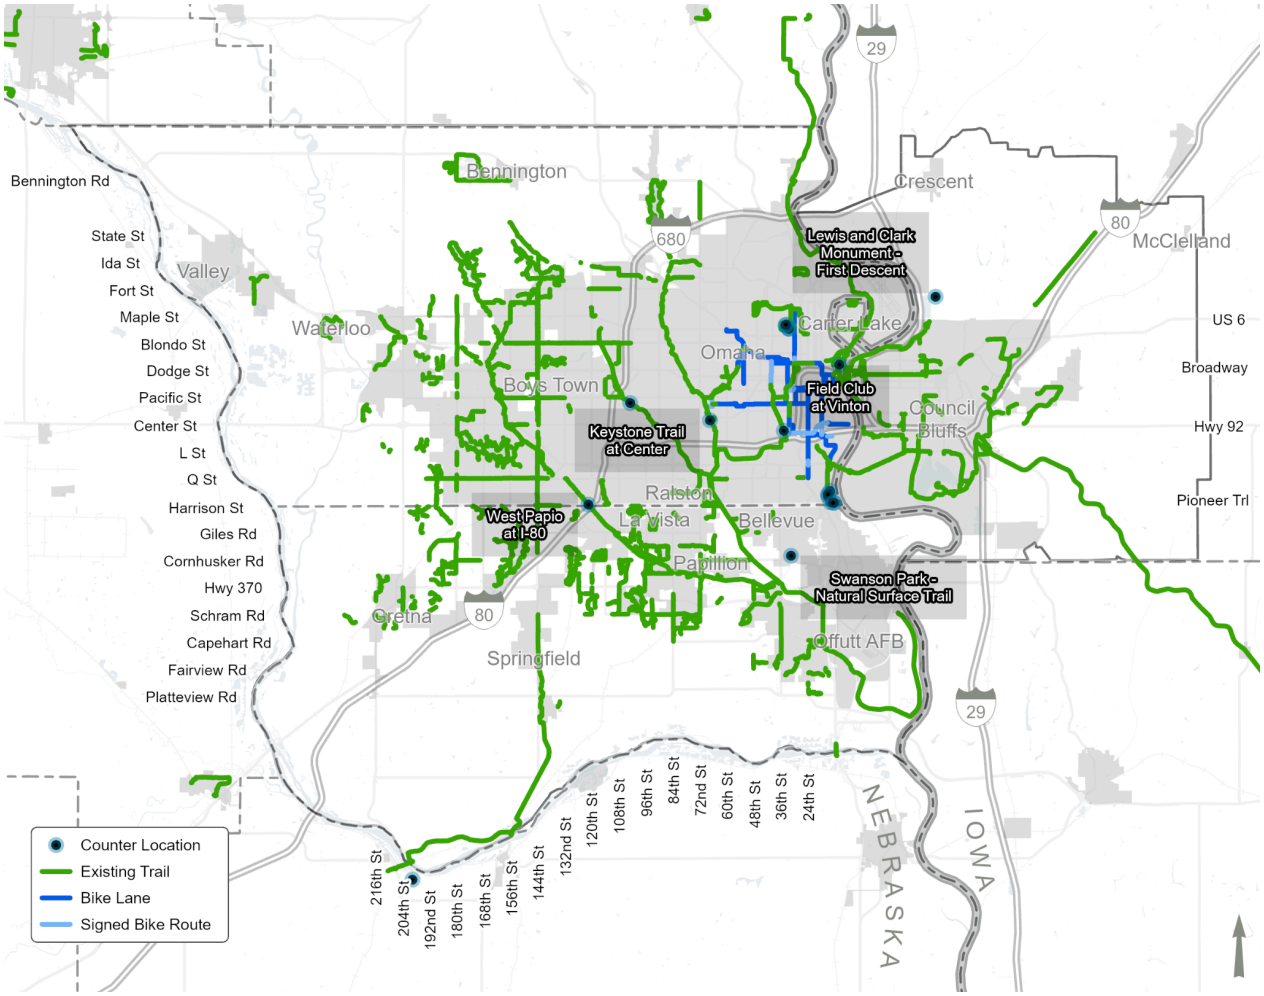

Multi-Modal Transportation

There are plenty of ways to get around our metro without always driving. Public transit, bicycling, walking, and other trip types provide an economical, sustainable alternative to automobile use.

Bicycle and Pedestrian Activity

MAPA and the City of Omaha, THOR (Trails Have Our Respect, and Fontenelle Forest partner to operate pedestrian and bicycle counters across the region. Permanent counters are installed at multiple locations to provide continuous counts of bike and pedestrian activity on our regional trail system. MAPA has had bike and pedestrian counters installed since 2016 and has expanded them to better represent the system regionally.

Figure *15: Regional Bicycle and Pedestrian Counts*

Regional trail use was evaluated using the Eco-Counter data with adjustments for counter failures and weather conditions. The counter analysis used only City of Omaha locations. Strava and BCycle provided additional information on trail and bicycle activity. Figure 16 and Figure 17 below highlight estimated average daily traffic for bicycles or pedestrians from the City of Omaha's permanent counters.

Figure *16: Estimated Annual Average Daily Pedestrian Volume*

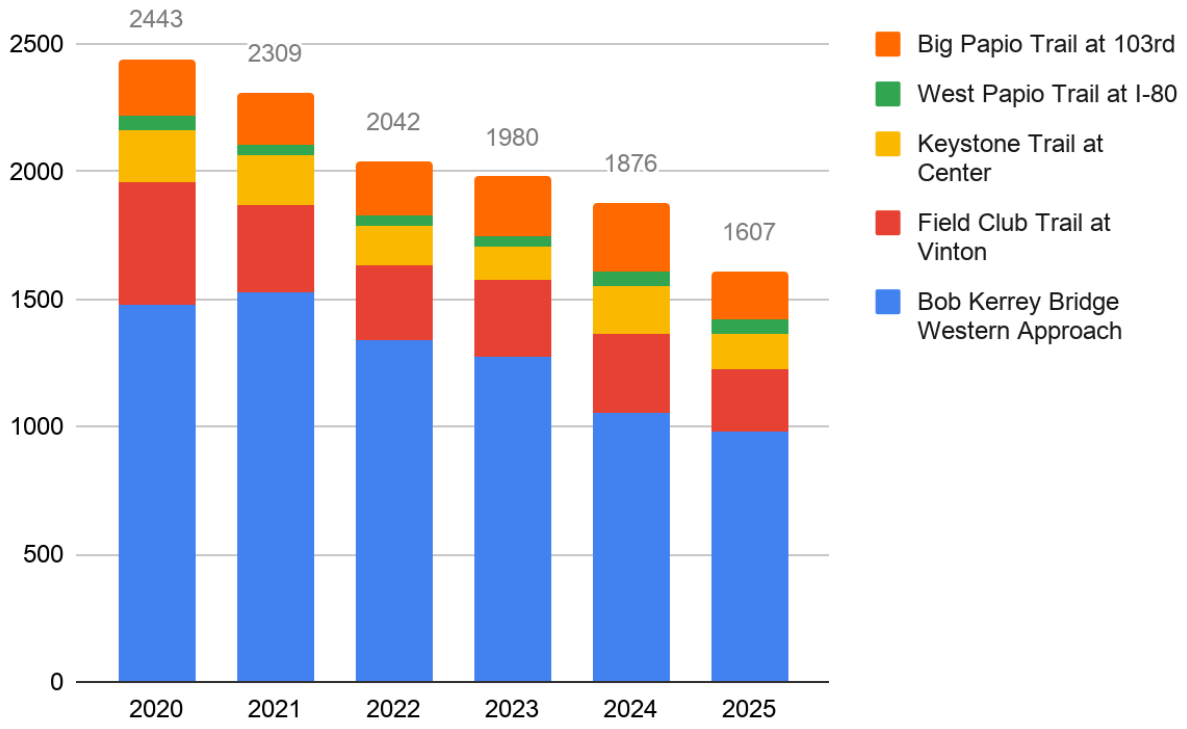

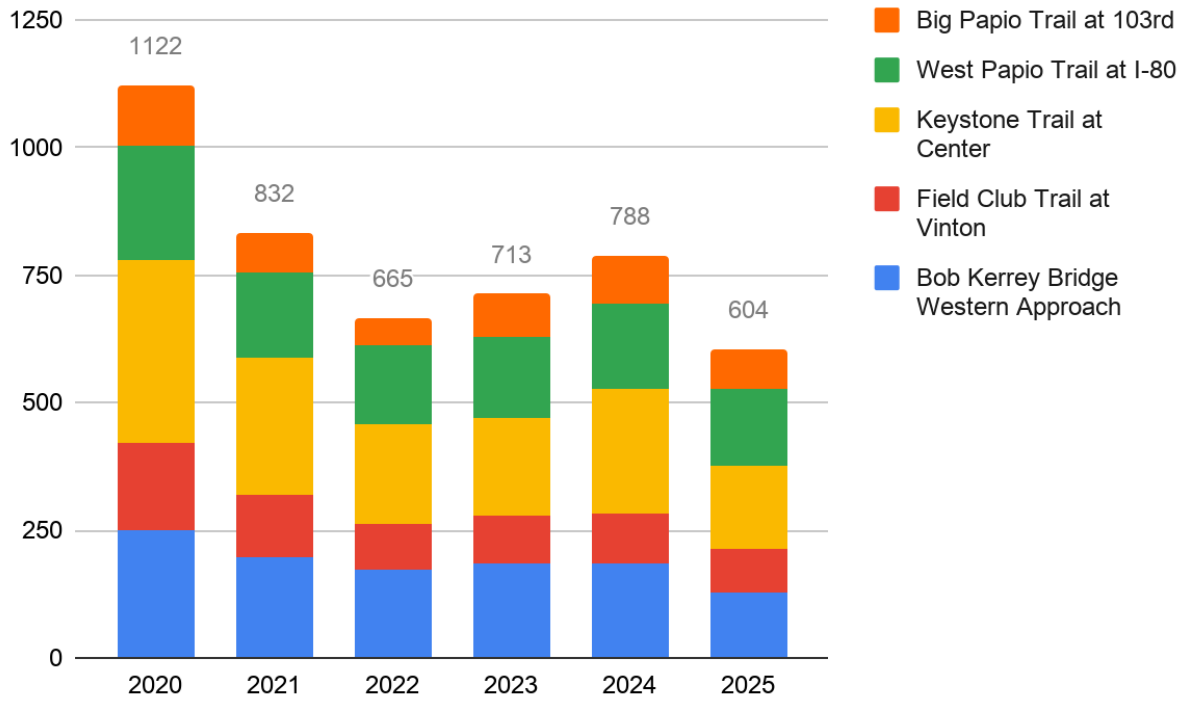

Figure 16 shows that average daily pedestrian counts at the five Omaha locations fell each year, from a combined 2,443 in 2020 to 1,607 in 2025. This represents a decrease of about 34%. The western approach to the Bob Kerrey Bridge remained the busiest pedestrian location throughout the period.

Bicycle counts did not follow the same steady decline. As shown in Figure 17, the combined daily average dropped from 1,122 in 2020 to 665 in 2022, then increased in both 2023 and 2024. The 2025 average of 684 was about 13% below 2024 but slightly above 2022.

Figure *17: Estimated Annual Average Daily Bicycle Volume*

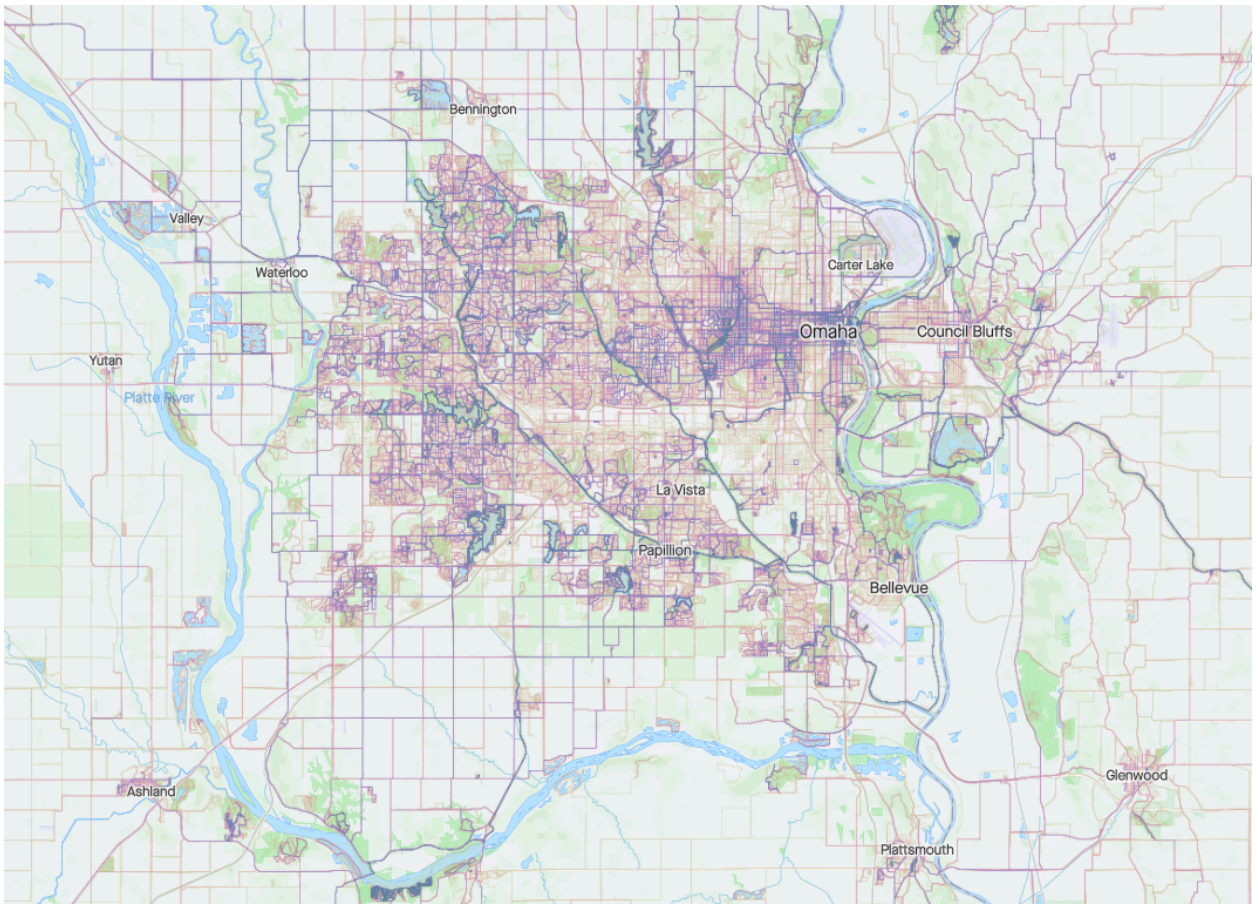

The high counts in 2020 coincided with increased outdoor activity during the pandemic. Lincoln, for example, reported a 45% increase in bicycle counts that year (City of Lincoln, n.d.). Later national findings suggest that recreational riding and commuting took different paths. In 2023, bicycle counts on recreational facilities decreased by 2.1%, while counts on commuter routes increased by 6.9% (Chapalain, 2024). Changes in daily routines may explain some of the lower counts in Omaha, but their effect was not measured in this report. The results apply to the monitored locations and do not establish a decline across the entire trail network or a return to pre-pandemic levels.

Strava Metroview

Another source of bicycle and pedestrian activity is the fitness app Strava. MAPA has access to publicly recorded activity data through the Strava Metroview platform. This dashboard visualizes user activity over time and provides tools for trend analysis. Activities are broken down into bicycling, running, walking, and hiking trips. Figure 18 provides a regional view of the Strava network within the MAPA region.

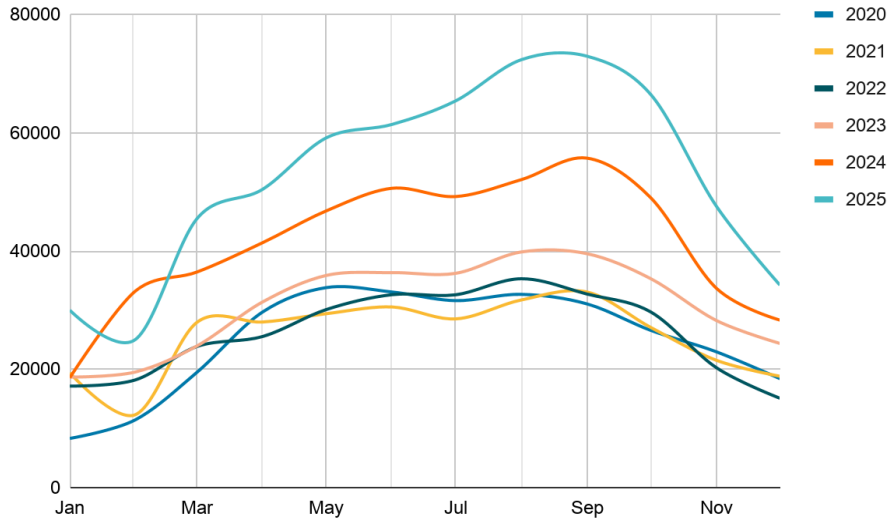

Figure *18: Strava Activity Heat Map*

This image contains aggregated and de-identified data from Strava Metro

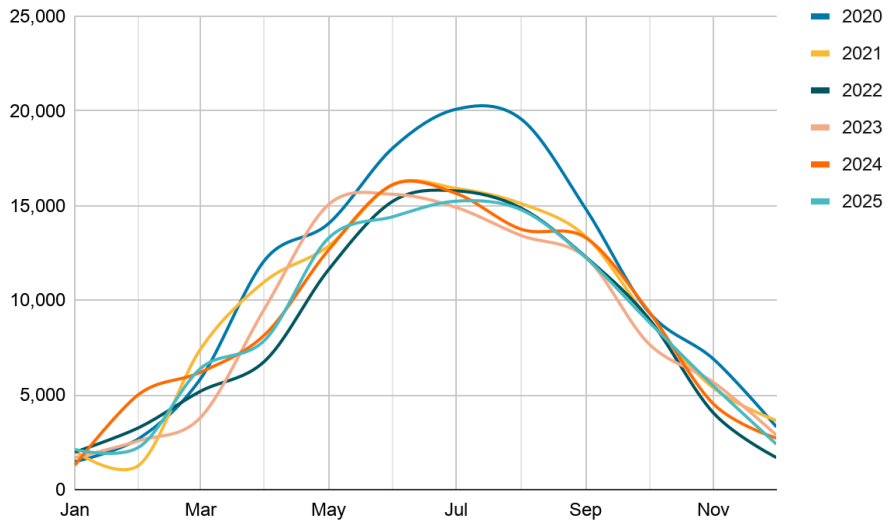

The app collects a sample of total activity, biased toward the Strava user base, whom they call ‘Athletes’. In 2025, the app flagged approximately 15% of regional activities as commutes, with the vast majority collected for recreational purposes. That said, it remains one of the largest sources of accessible bicycle and pedestrian activity data.

Figure *19: Public Run, Walk, Hike Activities Recorded on Strava*

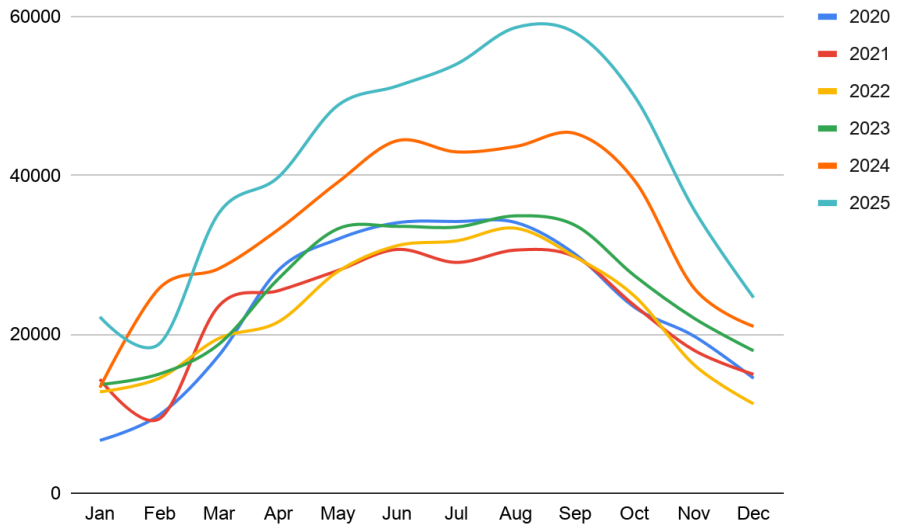

Figures 19 and 20 show different trends in activities recorded on Strava. Running, walking, and hiking increased substantially in 2024 and 2025. In Figure 19, monthly activities reached approximately 73,000 in August 2025, compared with a peak of about 55,000 in September 2024. Counts remained higher through much of 2025, with the largest differences occurring from late spring through early fall.

Figure *20: Public Bicycle Activities Recorded on Strava*

Bicycle activities in Figure 20 were more consistent across recent years. The highest monthly count occurred in July 2020, at approximately 20,000 activities. Summer peaks from 2021 through 2025 were generally between 15,000 and 16,000. Cycling activity rose through spring and declined after summer in each year, without the large increases seen in running, walking, and hiking.

Figure 21: Douglas County Recorded Activities

Figures 21 through 23 show the distribution of recorded activities by county. Douglas County had the largest totals, reaching approximately 59,000 activities in August 2025. Sarpy County peaked at about 21,000 that month, while Pottawattamie County reached approximately 7,400 in September. All three counties recorded their highest summer activity levels in 2025, following increases in 2024.

Part of this increase may reflect changes in Strava use rather than an equivalent increase in outdoor activity. Strava reported more than 120 million users worldwide in 2023 and more than 180 million in 2025. Walking also became its second most recorded activity in 2025 (Strava, 2024, 2025).

Figure 22: Sarpy County Recorded Activities

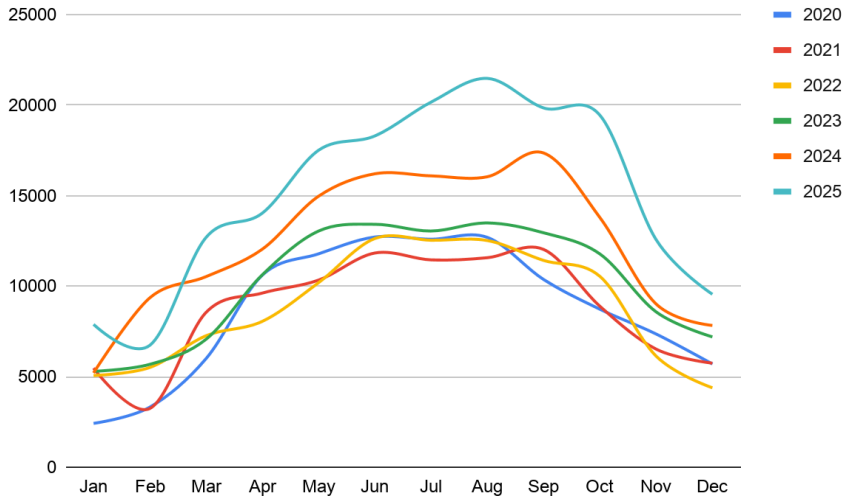

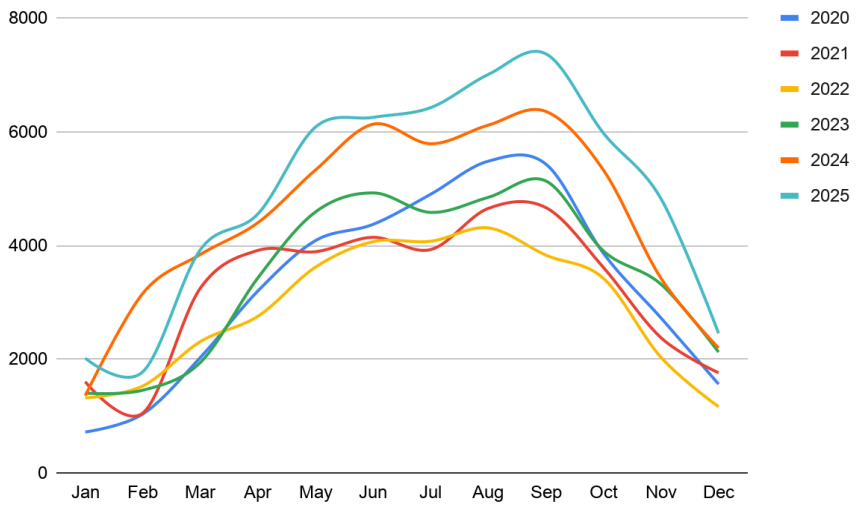

Figure 23: Pottawattamie County Recorded Activities

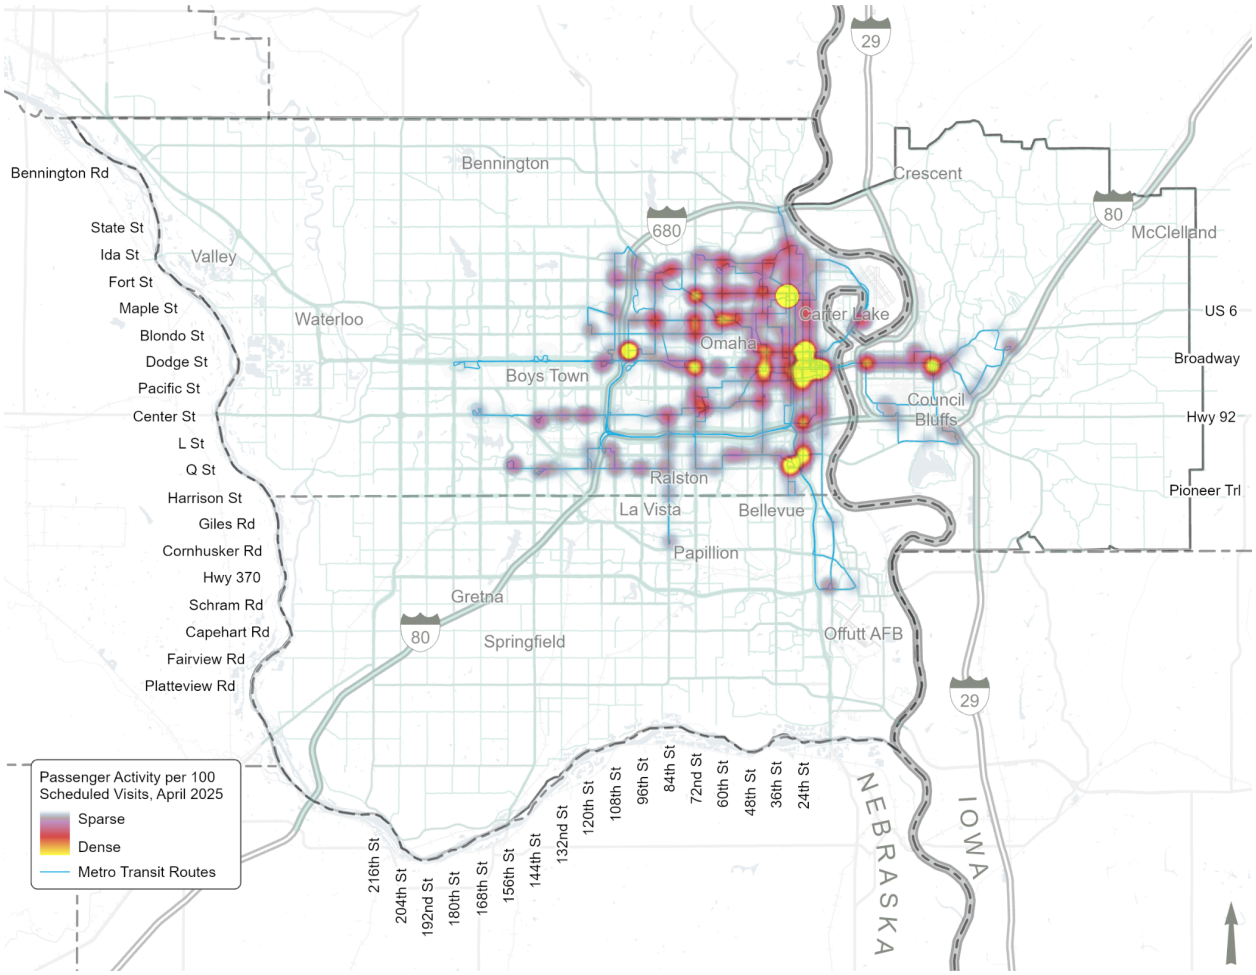

New facilities also provided more places to be active during this period. Gretna Crossing Park opened in September 2023 with walking and bicycle trails, while the FIRST AVE trail in Council Bluffs opened in stages during the reporting period (City of Gretna, n.d.; City of Council Bluffs, n.d.). These improvements provide local context, but we did not measure their contribution to the recorded increases. Strava remains a useful tool for identifying routes and seasonal patterns, but its totals should always be read alongside trail counter data rather than treated as a complete measure of trail use.

Transit

Metro Transit offers fixed route, express/commuter, circulator and origin-to-destination paratransit bus services throughout the Omaha metro, serving a territory of approximately 100 square miles. Contracted commuter services are offered to four other contiguous cities in Nebraska — Bellevue, Ralston, La Vista and Papillion — as well as Council Bluffs, Iowa.

Beginning in 2020 Metro began collecting Automated Passenger Count (APC) data on all of its buses. The productivity of each stop can be calculated by dividing the total number of passenger activities by the scheduled bus visits to each stop, as obtained from the Google Transit Feed Specification (GTFS) for Metro's fixed route service. Figure 24 shows stop productivity at each bus stop per 100 scheduled visits in April 2025.

Figure *24: Metro Ridership by Stop Productivity April 2025.*

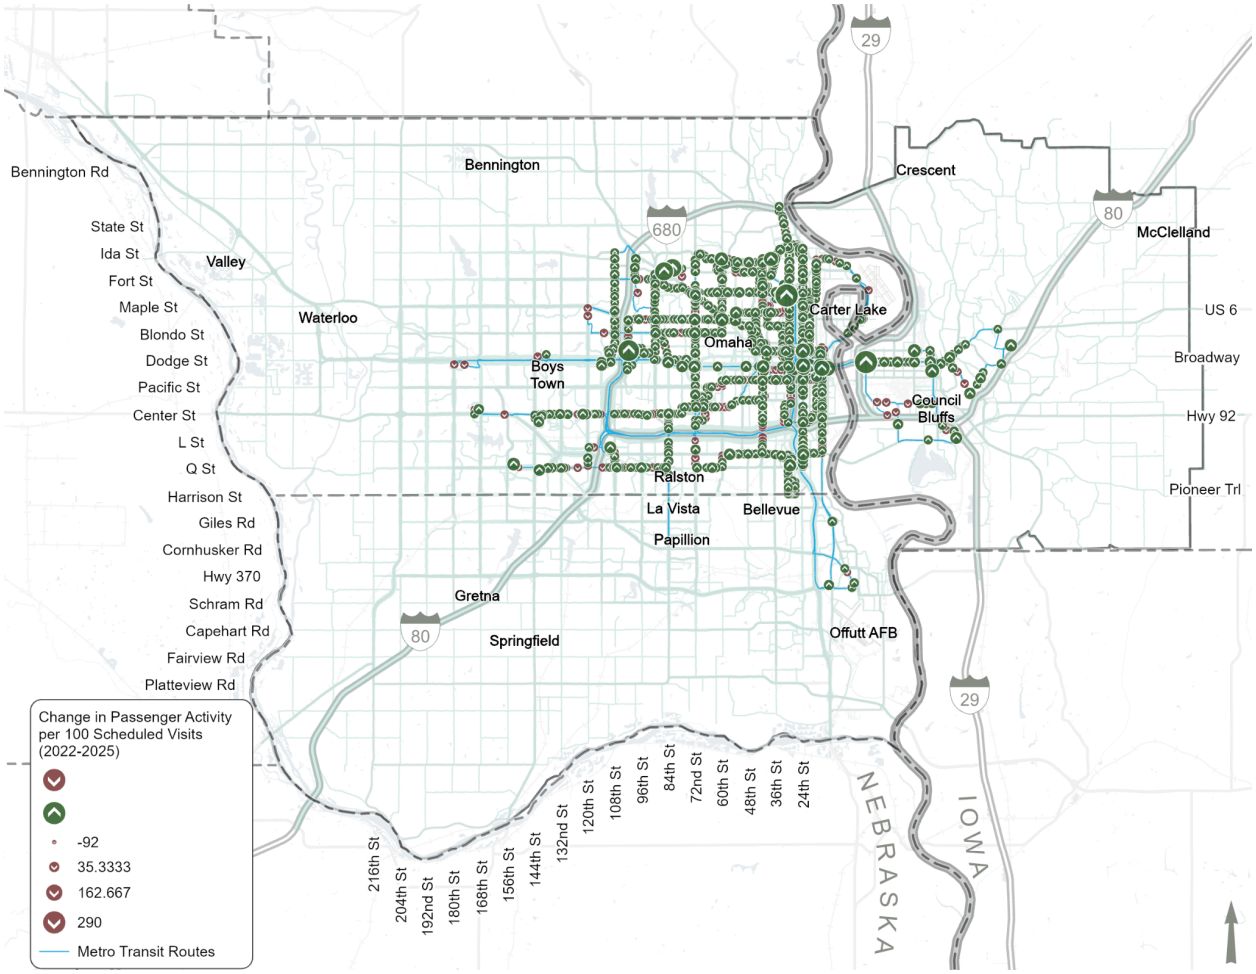

Stop productivity is highest in the urban core, and at Metro Transit Centers (Westroads to the west, Metro College Transit Center to the South, and the North Omaha Transit Center to the North), with the North Omaha Transit Center experiencing an average of 406 passengers activity per 100 scheduled visits across all 12 bays. Productivity at stops is lowest where transit routes operate along the fringes of the Metro service area (i.e., South and Northwest), as these areas are often served by express routes and/or operate at lower frequencies than routes within the urban core.

Over the past 4 years, ridership across Metro's service area has been increasing. Figure 26 depicts the ongoing change in ridership based on Metro Automated Passenger Count data, and Figure 25 shows the change in Metro ridership per 100 scheduled visits at each stop between April 2022 and April 2025.

In March 2020, the COVID-19 pandemic significantly affected transit service across the country. In the Omaha area, Metro Transit saw a correspondingly significant decrease in ridership. Rider behavior was likely affected by a combination of work from home policies and social distancing requirements brought on by the pandemic. Recent data indicate ridership may be returning to pre-pandemic levels, as shown in Figure 26.

Figure 25: *Change in stop productivity between April 2023 and April 2025*

Most stops showed an increase in stop productivity between 2022 and 2025, with the largest increase seen in Council Bluffs (35th and Broadway) with an average increase of 430 passengers per 100 scheduled visits, followed by the North Omaha transit center (406), 22nd & Cuming SE (345), Westroads ORBT station (269), and 153rd & Weir Park & Ride NW (261). Stop productivity decreased at all stops along Farnam due to re-routing of Metro's fixed route service to avoid streetcar construction.

Omaha Rapid Bus Transit

Metro opened Omaha Rapid Bus Transit (ORBT), the region's first bus rapid transit line, in November 2020. By its fourth anniversary in November 2024, ORBT had provided two million rides (Metro Transit, 2024). Figure 26 shows an overall increase in recorded passenger counts following the low levels seen in 2021. October 2024 had the highest count. Although April 2025 was lower, it remained above April 2024. ORBT accounted for approximately one in six recorded passenger counts in April 2025. ORBT serves as the spine of the transit system, connecting Westroads Mall with downtown Omaha along Dodge and Douglas Streets, with buses arriving every 10 minutes during most weekday daytime hours.

Figure 26: *Automated Passenger Counts Over Time*

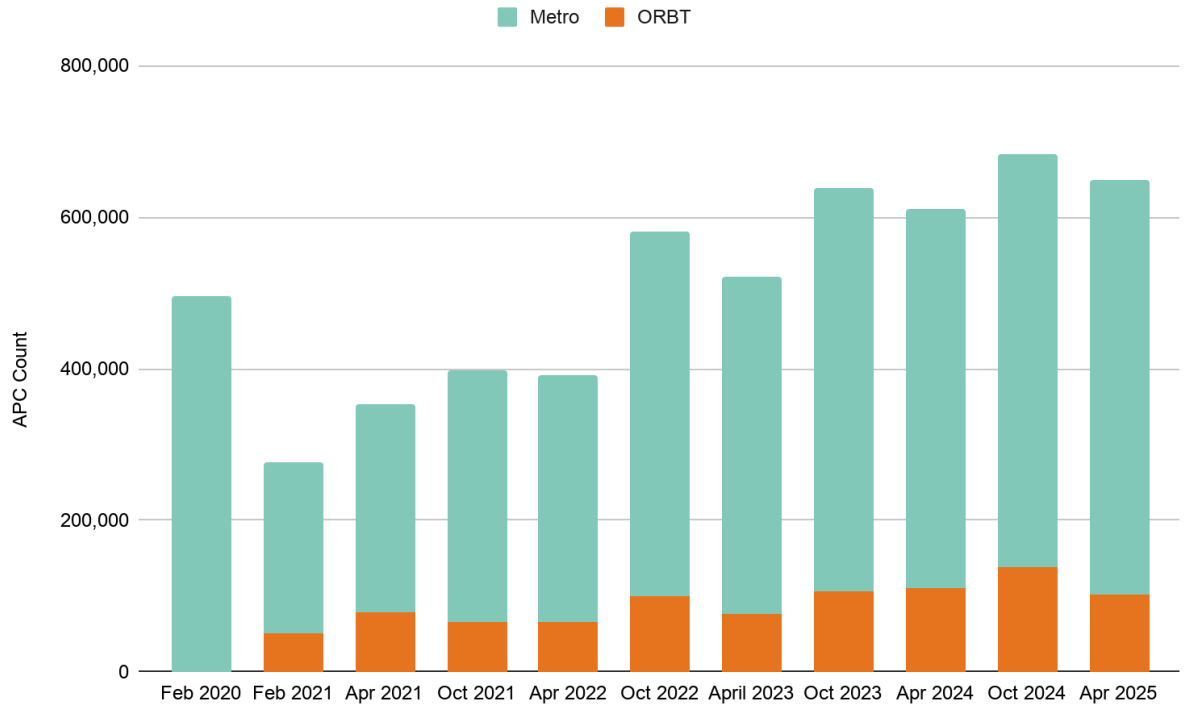

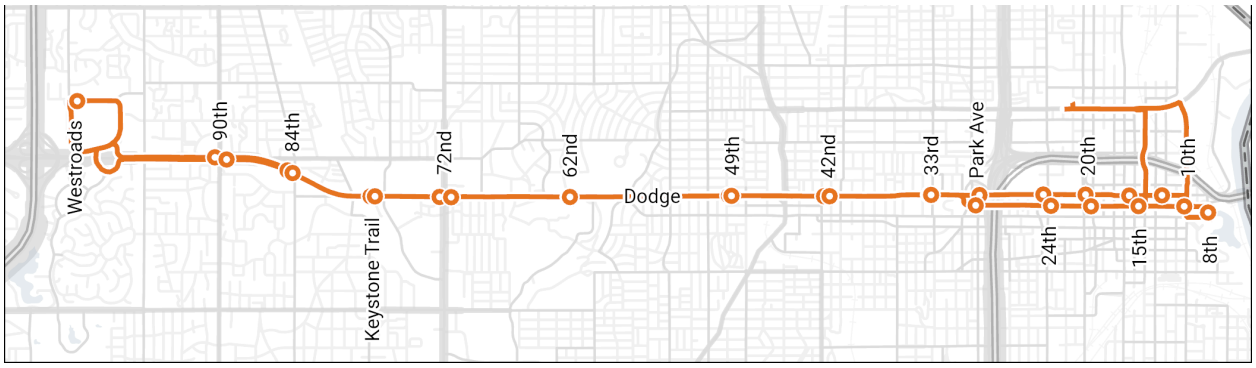

Figure 27 shows ORBT's connection. Raised platforms, boarding through three doors, and arrival displays make the service easier to use, while downtown bus lanes and traffic signal priority help reduce delays. Connections with other Metro routes at Westroads extend access beyond the ORBT corridor (Metro Transit, 2020).

Figure *27: Omaha Rapid Bus Transit (ORBT) System*

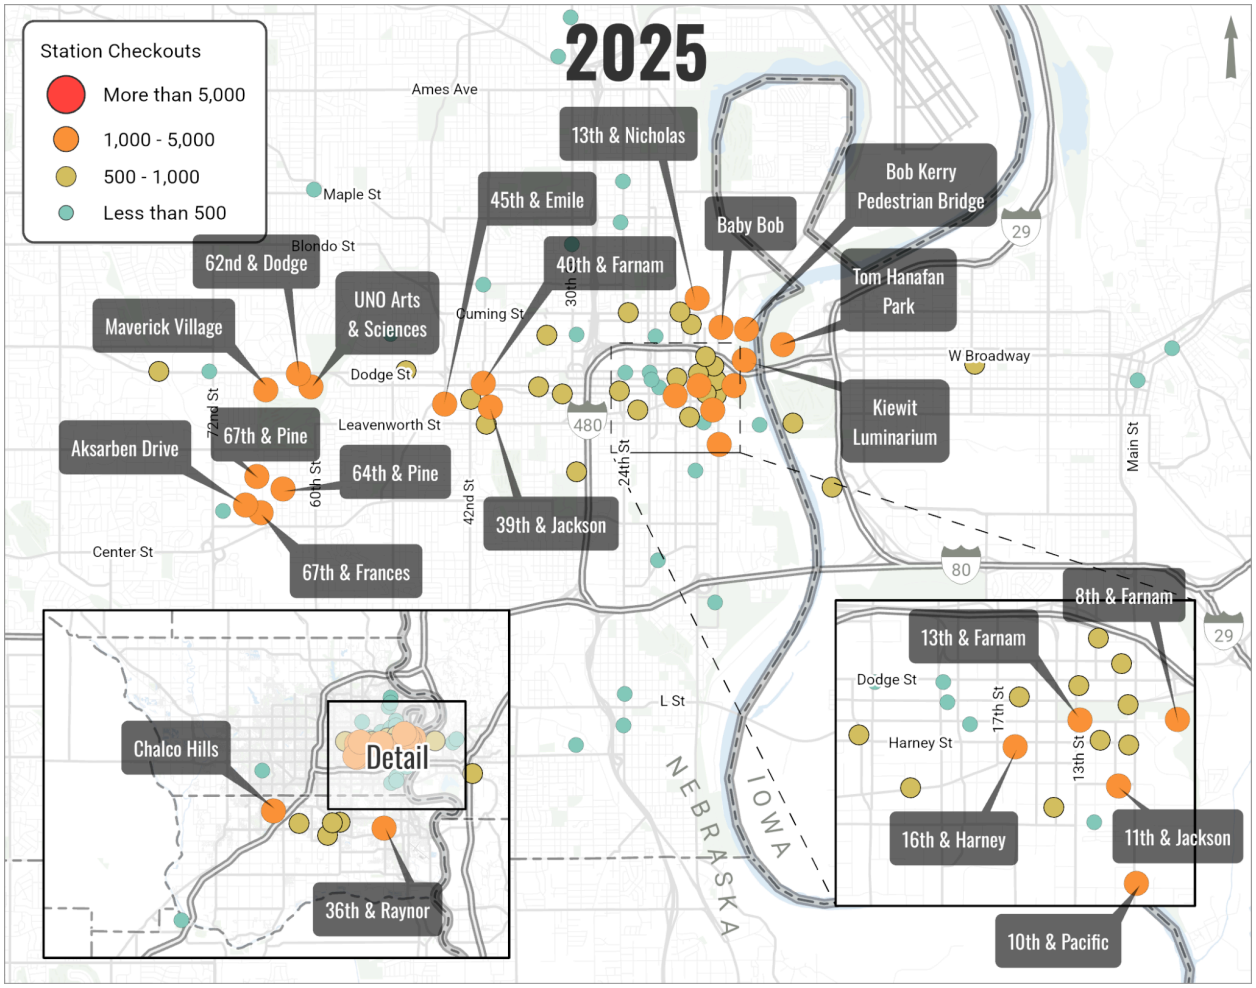

Other Modes

Regionally, travel options are becoming more diverse. Bike share and other micromobility platforms offer “last mile” travel options that are often paired with other modes to complete a trip. Ride-hailing services can replace typical automotive trips and may increase vehicle travel through deadheading, the extra miles required to travel between passenger pickups and drop-offs.

Heartland Bike Share

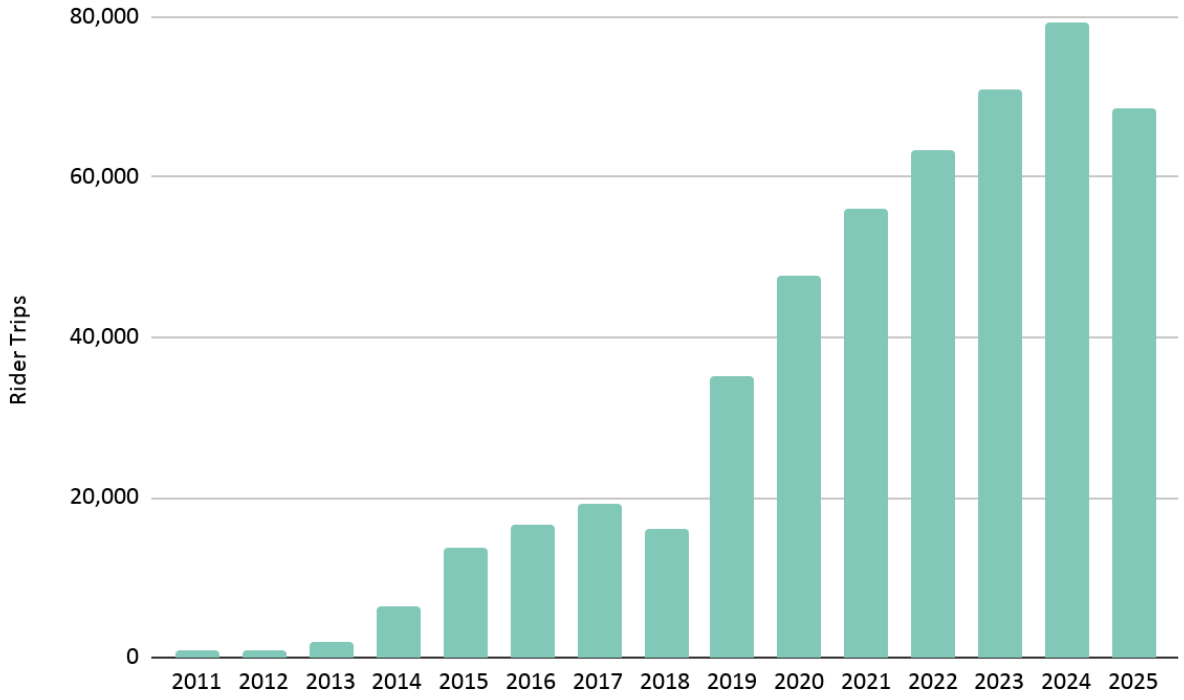

Heartland Bike Share operates a regional network of stations with shared bicycles that users can unlock and ride from station to station. The bicycles are designed to accommodate a variety of rider sizes and are available in human-powered and electric options. In 2025, Heartland Bike Share operated 80 stations in the Omaha Metro Area.

Figure *28: Bike Share Station Checkouts in 2025*

The Bob Kerrey Pedestrian Bridge has the highest station activity. Downtown, Midtown, and Aksarben also stand out as higher activity areas as shown in Figure 28. Newer stations deployed at regional parks such as Chalco Hills and trailheads like Twin Creek in Bellevue are also well used by the metro community.

Figure *29: Heartland Bike Share Rider Trips 2011 - 2025*

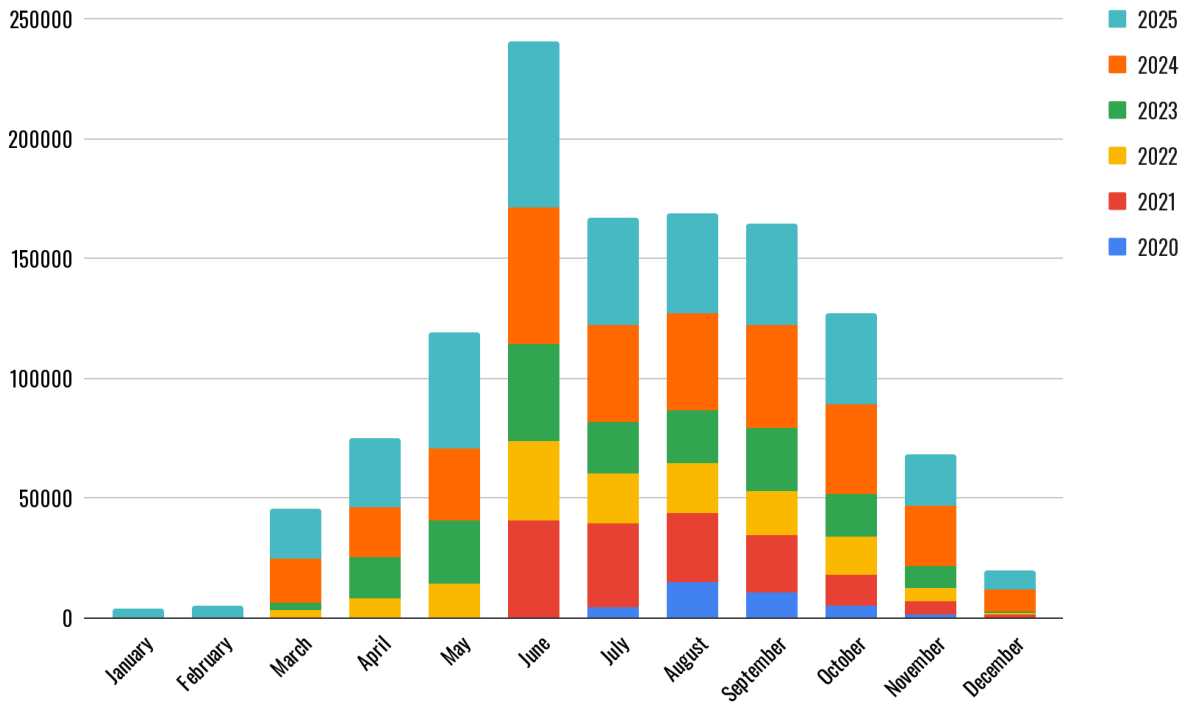

Heartland Bike Share has operated in the Omaha metro since 2011 and has grown significantly since its inception. Rider activity saw a boost following the pandemic and continues to increase as depicted in Figure 29. Not included in this analysis, Heartland Bike Share introduced the free rides program to metro residents in 2026.

Micromobility Service Providers

Micromobility includes bicycles, electric scooters, and other small devices used for short trips. Shared fleets allow users to rent a device rather than own one. Omaha began its electric scooter pilot in 2019, followed by a second pilot in 2020 that placed greater emphasis on rider safety, parking, and public feedback (Metro Smart Cities, n.d.). Park Omaha's annual scooter reports document use of the program. In 2025, a total of 373,541 scooter trips were recorded, primarily in Downtown, Midtown, Aksarben, and Benson.

Figure 30 shows monthly scooter trips from 2020 through 2025. Across the years shown, use was concentrated in the warmer months, with the highest combined total in June. Trips remained relatively high from July through September before declining in fall and winter. Warmer weather likely encourages riding, although scooter availability and operating schedules may also affect the monthly totals.

Figure 30: *Scooter Trips by Month 2020 - 2025*

The June peak also coincides with the Men's College World Series, held at Charles Schwab Field from June 13 through June 23 in 2025. Visitors traveling between the ballpark, parking areas, hotels, and downtown businesses may increase scooter use during this month. However, the monthly totals do not distinguish event trips from other travel, so the tournament's contribution cannot be measured.
